Conceptual Topos As Conceptual Cage: An Algebraic Topology of Meaning based on Conceptual Topology

Written by No Name Yet Exist Contact: Written Below

Introduction

Meaning was once considered fluid, ungraspable — a vapor that escaped the structures we tried to impose. But what if meaning does not escape? What if it moves, and that movement can be mapped, composed, and classified? This theory, Conceptual Topology (概念位相論) As Conceptual Topos, begins with a radical yet simple claim.

Meaning does not escape. It just topologizes within the abstract cage.

We no longer describe meaning merely through signs and chains of signifiers, but as flows — morphisms between concepts mediated by contextual anchors called Z-frames. These frames act as semantic coordinates, situating each concept within a space of possible interpretation.

A dog is not simply "a dog." It is interpreted through the semantic frame Z in which it is embedded.

dog | Domesticated

dog | Mammal

dog | Son

Or, as a morphism, computer → she | person

With the Z frame computer is interpreted as a historical computing worker (pre-digital era), resolving ambiguity via structural semantic framing.

In this model, concepts are objects, interpretive movements are arrows, and semantic coherence is topological.

We define categories like C|Z, where morphisms f: A \rightarrow B | Z are conceptual transformations under a shared meaning frame. We introduce operators like σ that model semantic shifting, generalization, or abstraction across frames and we show that these operators exhibit functorial and even Kan-extension-like behavior.

Meaning is no longer a mirage. It circulates within a space that is structured, closed, and composable. We are no longer chasing meaning. We are building it from its space.

Note: While we refer to "fibers" to describe morphic coherence over a shared Z-frame, this current formulation is not yet a strict fibered topos in the categorical sense. Rather, this document serves as the semantic scaffolding toward that formalization.

1. Fibered Conceptual Topology:

Fibered Conceptual Topology provides a conceptual geometric framework wherein each Z-frame (conceptual anchor) acts as a base space, with conceptual morphic flows forming fibers over these anchors. The Yonedalike interpretation captures concepts as bundles of conceptual relations within and across Z-frames. This fibered structure serves as the foundation for further constructions in Conceptual Topos.

```
CT := (C, B, π: E → B, Fb := π<sup>-1</sup>(b), A ≅ b ∪ Nat(Hom(-, A), Fb))
Where:
   - C is the category of concepts (objects = words or concepts)
   - B is the base space of Z-frames (conceptual continuity anchors)
   - E is the total conceptual space (word vector embedding space)
   - π projects each concept to its conceptual base (Z-frame)
   - Fb is the fiber (conceptual morphic chain) over a base b
   - A ≅ b ∪ Nat(Hom(-, A), Fb) interprets each concept A via its morphisms relative to its Z-frame b (Yoneda perspective defined in appendix)
```

1.1. A Z-framed Conceptual Category

A Z-framed Conceptual Category is a structure (C, Z, Hom, id, o).

- Ob(C) is a set of conceptual entities.
- Z is a set of conceptual frames.
- Hom(X, Y | Z) is the set of morphisms from X to Y within Z-frame.
- For each X, there exists an identity morphism id_X|Z: $X \rightarrow X \mid Z$ or id_X: $X \rightarrow X \mid X$.
- Composition is a partial operation defined as

```
For f: X \rightarrow Y | Z<sub>1</sub> and g: Y \rightarrow Z | Z<sub>2</sub>, g \circ f: X \rightarrow Z | Z<sub>3</sub> is defined iff \exists Z<sub>3</sub> \in Z such that Z<sub>1</sub> \subseteq Z<sub>3</sub> and Z<sub>2</sub> \subseteq Z<sub>3</sub>
```

Z-Frame

Z-frame has multi-functionality as a conceptual frame: Category, Fiber and Morphism level object. We define a Z-Indexed Fibered Conceptual Category as a tuple

```
(C, Z, π: C → Z)

Where:
    C: A category of conceptual morphisms (objects: concepts, morphisms: semantic transformations)
    Z: A category of conceptual frames (Z-frames), representing interpretive contexts or domains
    π: A functor projecting each morphism in C to its conceptual frame in Z
```

Object Level Z-Frame Structure

```
Let:
Ob(C) be a set of conceptual entities (dog, she, king, ...)
Ob(Z) be a set of semantic frames (Domesticated, Mammal, Abstract, ...)
Each morphism in C is typed as
f: A \rightarrow B \mid Z \in Hom(A, B \mid Z)
This is realized through a retractive structure mediated by Z
g: Z \rightarrow A
such that
g \circ f \cong id\_A \mid Z
In diagrammatic terms
   Α
   | \
   Z \rightarrow A (g o f = id A | Z)
Alternatively, to express conceptual flow under Z
f: A \rightarrow Z
g: Z \rightarrow B
such that
g \circ f \cong A \rightarrow B \mid Z
This means that A is transformed to B under the interpretation frame Z. The flow
between A and B is mediated by Z, and Z ensures that the interpretation of both A
and B is consistent under the same frame.
```

Disambiguation and Structural Integrity When multiple interpretations (or semantic frames) exist such as *computer*, Z acts as a disambiguating factor, ensuring that the meanings of A and B are not left to chance but are structurally ensured by their relationships to Z.

Example:

```
computer → she | person
```

Without Z, computer may refer to a machine, a metaphor, a role, or even ambiguity between literal and historical meanings.

With Z = person, computer is interpreted as a historical computing worker (pre-digital era), resolving ambiguity via structural semantic framing.

Fibered Structure

```
For each Z \in Ob(Z), define the local fiber: \pi^{-1}(Z) := \{ f \in Mor(C) \mid \pi(f) = Z \} Over the total base Z, the full fibered category is: \pi^{-1}(Z) := \{ f_i \in Mor(C) \mid \pi(f_i) = Z_i \text{ for some } Z_i \in Ob(Z) \}
```

This is the subcategory C|Z, where all morphisms are constrained to operate within the same Z-frame.

Functoriality

 π must satisfy the functor laws

```
For any identity morphism id\_A|A in C \pi(id\_A|A) = id\_Z|Z For any composable morphisms f\colon A\to B\mid Z_1, g\colon B\to C\mid Z_2 with Z_1, Z_2\subseteq Z, the composition is g\,\circ\, f\colon A\to C\mid Z and: \pi(g\,\circ\, f)=Z Here, Z is the least upper bound (or unifying context) of Z_1 and Z_2.
```

Z-Frame Subsuming Composition ($Z \subseteq Z'$) Although f is originally defined over Z, due to the inclusion Z $\subseteq Z'$, the composite $g \circ f$ can be interpreted as an internal composition in the superordinate category Z'.

```
Let Z ⊆ Z'
f: A → B | Z
where:
  f_1: A \rightarrow Z
  f_2: Z \rightarrow B
  f = f_2 \circ f_1
   thus, A \rightarrow Z \rightarrow B
g: B \rightarrow C \mid Z'
where:
   g_1: B \rightarrow Z'
  g_2: Z' \rightarrow C
   g = g_2 \circ g_1
  thus, B \rightarrow Z' \rightarrow C
Z subsuming composition is expressed as follows.
g \circ f = g_2 \circ (g_1 \circ f_2) \circ f_1
h:= g_1 \circ f_2: Z \rightarrow Z'
g \circ f \mid Z' = g_2 \circ h \circ f_1
```

In Diagram:

In NL Diagram:

Z-Frame Lifting via Kan Extension (Z ⊈ Z')

In the case of $Z \nsubseteq Z'$, Left Kan Extension ensures conceptual flow structurally.

Category:

We define a Z-framed Conceptual Category **C|Z** (e.g. dog|Domesticated), C|C in simple notation **Concept** (e.g. Dog, Button...), as a category enriched over semantic frames Z.

Notation: We denote a morphism f: $X \to Y$ mediated by Z-frame as f: $X \to Y \mid Z$. This represents a meaning-preserving conceptual flow within the frame Z.

Objects

Ob(C|Z): A set of conceptual entities (lexical terms, abstract notions). Examples: dog, she, computer, king, etc.

Morphisms

Each morphism is defined mediated by a Z-frame. **Hom(X, Y | Z)** = { f | f: $X \rightarrow Y | Z$ }, where $Z \in Ob(Z \text{ Frames})$ represents a semantic anchor or contextual frame.

A morphism f: $X \to Y \mid Z$ is interpreted as "X conceptually maps to Y within the semantic continuity defined by Z." Z gives the interpretive coherence or semantic clarification(e.g., dog \to pet | Domesticated).

Composition

Composition is defined only within a shared Z-frame or subsuming Z frame of local Z frames.

1. Within the same Z-frame If f: A \rightarrow B | Z, g: B \rightarrow C | Z, then g \circ f is defined iff Z is shared.

```
f: computer → smartphone | Gadget
g: smartphone → mobile GPS | Gadget
g ∘ f = computer → mobile GPS | Gadget
```

2. Across compatible Z-frames (via σ-mediated composition)

Composition across different Z-frames (i.e., σ -mediated composition) is possible when the individual Z-frames are compatible under a higher semantic frame. This higher frame Z must be able to subsume both the local frames Z_1 and Z_2 by the conditions $Z_1 \subseteq Z$ and $Z_2 \subseteq Z$. This condition ensures that both morphisms can coexist within the same larger context, preserving the continuity of meaning across frames.

If f: A \rightarrow B | Z₁, g: B \rightarrow C | Z₂, then g \circ f is defined iff there exists a higher frame Z such that Z₁ \subseteq Z and Z₂ \subseteq Z.

```
f: computer → smartphone | Gadget
g: match → knife | Tool

If there exists a higher frame Instrument that subsumes both Gadget and Tool,
then the composite morphism becomes

g ∘ f = computer → knife | Instrument
where Instrument ⊇ Gadget, Tool
```

This composition is associative within a Z-frame

```
If: f: A \rightarrow B | Z, g: B \rightarrow C | Z, h: C \rightarrow D | Z
then: (h \circ g) \circ f | Z = h \circ (g \circ f) | Z.
```

This guarantees that within a single Z-frame, composition behaves as expected according to the standard rules of category theory.

σ-mediated Composition:

In the case of σ -mediated composition, associativity holds when all involved Z-frames are subsumed by a common higher Z-frame.

```
Let f: A \to B \mid Z_1, g: B \to C \mid Z_2, and h: C \to D \mid Z_3 (h \circ g) \circ f \mid Z = h \circ (g \circ f) \mid Z is valid where Z_1 \subseteq Z, Z_2 \subseteq Z, and Z_3 \subseteq Z.
```

This ensures that all morphisms can coexist within the same conceptual space, and the meaning flow is preserved across the frames.

Example:

If f: computer \rightarrow smartphone | Gadget, g: smartphone \rightarrow mobile GPS | Gadget, and h: mobile GPS \rightarrow navigation | Travel, then the composite morphism is defined as

```
h ∘ (g ∘ f) | Travel = computer → navigation | Travel where: Gadget ⊆ Travel is defined
```

Here, Instrument is a higher Z-frame that subsumes both Gadget and Travel.

Let C|Z be a Conceptual Category with partial composition o|Z.

Partial Composition in Z-Framed Category

```
Typing judgment f\colon A\to B\mid Z\in Hom(A,\ B\mid Z) Composition judgment If\ f\colon A\to B\mid Z_1\ \text{and}\ g\colon B\to C\mid Z_2, and \exists Z such that Z_1\subseteq Z and Z_2\subseteq Z then define: g\circ f\colon A\to C\mid Z This defines a partial composition operation: \circ\colon Hom(A,\ B\mid Z_1)\times Hom(B,\ C\mid Z_2) \to Hom(A,\ C\mid Z)
```

Identity Morphism

In Category Theory, Identity Morphism is always defined.

```
For every morphism f: A → B,
there exist identity morphisms id_A: A → A and id_B: B → B such that
f ∘ id_A = f
id_B ∘ f = f
```

However, in Conceptual Topology, morphisms are mediated by Z frame, thus the identity morphis is not always given unless Z is defined.

Two Types of Identity Morphism in Conceptual Topology

1. f: $X \rightarrow X \mid X$ (Category-theoretic identity)

```
For every object X, there exists a mediated identity morphism
  id_X: X → X | Z

such that for Z = X (i.e., the identity is mediated by the object itself),
we define
  f: X → X | X
  f ∘ id_X = f
  id_X ∘ f = f

e.g. f: dog → dog | dog
```

2. f: $X \rightarrow X \mid Z$ (Mediated identity with conceptual flow)

Since the identity morphism passes through an external anchor point, the identity morphism is defined quasi-identical.

```
e.g. dog → perro | собака
```

Simplified Form of Identity Morphism:

```
    f: X → X | X (Category-theoretic identity)
    In simplified form: X
    or more explicitly: id_X
```

2. f: $X \rightarrow X \mid Z$ (Mediated identity with conceptual flow) In simplified form: $X \mid Z$

Mirror Morphism Definition:

Each mirror maps conceptual transitions across vocabularies while preserving morphic identity up to rupture —that is, it allows for conceptual divergence that still respects underlying structural continuity, even if exact invertibility is not preserved.

```
\begin{array}{l} f: X \to Y \quad | \ Z \in D_i \\ f': X' \to Y' \quad | \ Z \in D_{i+1} \\ \to X' \neq X, \ \text{but } \text{cod}(f) = \text{cod}(f') \quad | \ \text{CD (CD = codomain)} \end{array} 
 We define f' as a mirror-correspondent morphism of f under a given Z-frame, if and only if:  \begin{array}{l} \exists Z: \ \text{rupture}(f, \ f' \mid Z) \neq \varnothing \\ \land \ \text{cod}(f) = \text{cod}(f') \quad | \ \text{CD} \end{array}
```

Note: Z: rupture(f, f' | Z) $\neq \emptyset$ means that there exists a Z-frame under which f and f' exhibit structural divergence—i.e., they are not fully invertible but still converge at the codomain level.

For example, let Z = abstraction. This allows a conceptual transition from $girl \rightarrow she$ and $puppy \rightarrow dog$, treating them as mirror morphisms under a shared conceptual frame.

However, if we take Z = agency, a rupture emerges: $puppy \rightarrow dog$ lacks agency, while $girl \rightarrow she$ retains it. Hence, $rupture(f, f' \mid agency) \neq \emptyset$, yet f and f' still align toward the same codomain (e.g., mammal).

Quasi-Natural Transformation of Meaning Systems

A **Morphic Chain Mirror** is a contextual correspondence between two morphic chains drawn from distinct but meaning-aligned vocabularies. This correspondence is realized through a **quasi-natural transformation** under a shared intermidiating Z-frame.

```
\begin{array}{lll} \eta\colon D_i \Rightarrow D_{i+1} & \mid \mathsf{CD}\ (\mathsf{CD} = \mathsf{codomain}) \\ \eta_{\mathsf{L}}\mathsf{X} \circ D_i(\{f_1 \mid \mathsf{Z}_1, \, \ldots, \, f_n \mid \mathsf{Z}_n\}) \approx D_{i+1}(\{f'_1 \mid \mathsf{Z}_1, \, \ldots, \, f'_n \mid \mathsf{Z}_n\}) \circ \eta_{\mathsf{L}}\mathsf{Y} \mid \mathsf{CD} \\ \text{for all } f_j\colon \mathsf{X}_j \to \mathsf{Y}_j \mid \mathsf{Z}_j \in \mathsf{D}_i, \\ \text{where } f'_j\colon \eta_{\mathsf{L}}\mathsf{X}(\mathsf{X}_j) \to \eta_{\mathsf{L}}\mathsf{Y}(\mathsf{Y}_j) \mid \mathsf{Z}_j \\ \end{array} Then, \eta is said to be a quasi-natural transformation under the Z-frame i.e. \eta \in \mathsf{Mor}(\mathsf{C}) where C is the contextual meaning category Example: \eta\colon \mathsf{girl} \to \mathsf{puppy} \mid \mathsf{Z} = \mathsf{Baby}
```

Diagram:

1.2. σ Operator as Functor

Definition: Conceptual Shifting Morphism (σ)

```
σ: D(X<sub>n-1</sub> | X) → D(X<sub>n-1</sub> | X)
such that σ ⊕ f ∈ M|Z if and only if type compatibility holds:

∀ A, B, (A → B) ∘ σ(X) is valid if:

( A >> X or X >> A )
and
( B >> X or X >> B )

Definition: Subsumption
A >> X ≡ A ⊑ X

Definition: SubsumedBy
X >> A ≡ X ⊑ A

Example:
king → king >> human → human
⇒ king >> human → valid

human → human >> queen → queen
⇒ human >> queen → valid
```

Conceptual Operators

Conceptual Operator σ modifies morphism as follows.

Conceptual Morphism Set Operators

```
Addition (\oplus): \sigma(X). \ \oplus (f, A_{n-1} \mid Z): D(A_{n-1} \mid Z) \rightarrow D(B_{n-1} \mid Z) \mid Z \sigma(X). \ \oplus (f_1, f_2): A_{n-1} := \{f_1, f_2\} Subtraction (\ominus): \ominus: A_{n-1} \ \ominus \{f_i\} \sigma(X). \ \ominus (f, A_{n-1} \mid Z): D(A_{n-1} \mid Z) \rightarrow D(B_{n-1} \mid Z) \mid Z - \ \oplus \ \text{operator is } \sigma_{\text{safe}} \ \text{if } Z \ \text{alignment is preserved.} - \ \ominus \ \text{operator is potentially } \sigma_{\text{unsafe}} \ \text{but can be } \sigma_{\text{safe}} \ \text{if resulting chain preserves the underlying morphic continuity } Z.
```

Example

```
{Royalty, Male, Human} ⊖ {Male} ⊕ {Female}
= {Royalty, Female, Human}
= queen
```

Conceptual Mapping

```
C\_{chain} = \{ \ f_1, \ f_2, \ \dots, \ f_n \ | \ Z \} \in D(C_{n-1} \ | \ Z) \sigma(X) \colon D(A_{n-1} \ | \ Z) \Rightarrow D(B_{n-1} \ | \ Y) \ | \ Z, \ Y \in CD where: D(A_{n-1} \ | \ Z) = \text{source morphic chain} D(B_{n-1} \ | \ Y) = \text{target morphic chain} CD = \text{codomain alignment (conceptual anchor)} \sigma(X) \text{ is not strict functorial} \Rightarrow \text{quasi-alignment under conceptual equivalence} \sigma(X) \approx \eta \colon D_i \Rightarrow D_{i+1} \ | \ CD \ (Quasi-Natural \ Transformation \ interpretation) Example: \\ \sigma(X). \ > (\text{puppy} \Rightarrow \text{dog} \Rightarrow \text{mammal} \ | \ Canine, \ Human) \ \ni \text{girl} \Rightarrow \text{she} \Rightarrow \text{mammal} \ | \ Human} where: canine, Human \in Mammal
```

Identity Morphism of σ

```
word is word thus: word \cong Nat(Hom(-, word | Word), Fib(word))  \sigma_{id}(Z). \  \, \text{OP}(X,Z) = \sigma \, \text{ such that } \sigma(f,Z) = f \, \text{ for all } f \in \text{Hom}(X,\,X \mid Z) \, \text{ unless OP is } \sigma_{unsafe} \, \text{ such that word is not a word: } \sigma(\text{Word}). \, \text{Not}(\text{word} \rightarrow/\text{word})   \sigma_{id}(\text{Word}). \  \, \text{OP}(\text{word},\,\text{Word}) = \text{word}   \sigma_{id}(\text{Word}). \  \, \text{OP}(f,\,\text{Word}) = f \, \text{ for all } f \colon \text{word} \rightarrow \text{word} \mid \text{word}   \sigma_{ince}: \  \, \text{M} \mid Z = \{ f_n \circ \ldots \circ f_1 \mid \text{all } f_i \colon X_i \rightarrow X_{i+1} \mid Z \land \forall i, j \colon f_i \cong f_j \mid Z = \text{Word} \}   \sigma_{id}(\text{Word}) \in \  \, \text{M} \mid \text{Word}   \sigma_{id}(\text{Word}) \circ \  \, \sigma_{id}(\text{Word}) = \sigma(\text{Word})   \sigma_{id}(\text{Word}) \circ \sigma_{id}(\text{Word}) = \sigma(\text{Word})
```

Associativity of σ

```
\begin{split} &\sigma_1(Z). \ \mathsf{OP}(\mathsf{D}(\mathsf{A}_{\mathsf{n-1}} \mid \mathsf{Z}), \ \mathsf{Z}) = \mathsf{D}(\mathsf{Z}_{\mathsf{n-1}} \mid \mathsf{Z}) \\ &\sigma_2(\mathsf{Z}). \ \mathsf{OP}(\mathsf{D}(\mathsf{B}_{\mathsf{n-1}} \mid \mathsf{Z}), \ \mathsf{Z}) = \mathsf{D}(\mathsf{Z}_{\mathsf{n-1}} \mid \mathsf{Z}) \end{split} Then the composition \sigma_2 \circ \sigma_1: &\sigma_-\mathsf{comp}(\mathsf{Z}). \ \mathsf{OP}(\mathsf{D}(\mathsf{Z}_{\mathsf{n-1}} \mid \mathsf{Z}), \ \mathsf{D}(\mathsf{Z}_{\mathsf{n-1}} \mid \mathsf{Z})) = \mathsf{D}(\mathsf{Z}_{\mathsf{n-1}} \mid \mathsf{Z}) \end{split} where: \mathsf{OP} is not \sigma_-\mathsf{uns} afe and under shared \mathsf{Z} frame &\mathsf{Associativity} \\ \mathsf{For all} \ \sigma_1(\mathsf{Z}), \ \sigma_2(\mathsf{Z}), \ \sigma_3(\mathsf{Z}) \ \mathsf{such that their domains/codomains match for composition: } \\ &(\sigma_3 \circ \sigma_2) \circ \sigma_1 = \sigma_3 \circ (\sigma_2 \circ \sigma_1) \end{split} Thus, \sigma composition operator is associative under Monoid structure.
```

Example:

```
Let \sigma_1 = \sigma(\text{Mammal}). >>(canine \rightarrow mammal, Life) = (life \rightarrow life | Life)

Let \sigma_2 = \sigma(\text{Mammal}). >>(mammal \rightarrow animal, Life) = (life \rightarrow life | Life)

Let \sigma_3 = \sigma(\text{Mammal}). >>(animal \rightarrow livingBeing, Life) = (life \rightarrow life | Life)

Conclusion:

(\sigma_3 \circ \sigma_2) \circ \sigma_1 = \sigma_3 \circ (\sigma_2 \circ \sigma_1) = (\text{life} \rightarrow \text{life} | \text{Life})
```

1.3. σ Operator as Kan Extension

Functorial Properties of σ mapping

```
A Functor F: C \rightarrow D is a mapping between categories satisfying:

- Object mapping: For each X \in Ob(C), F(X) \in Ob(D)

- Morphism mapping: For each f: X \rightarrow Y \in Mor(C), F(f): F(X) \rightarrow F(Y) \in Mor(D)

- Identity preservation: F(id_X) = id_{F(X)}

- Composition preservation: F(f \circ g) = F(f) \circ F(g)

We define \sigma: D(A<sub>n-1</sub> | Z) \rightarrow D(B<sub>n-1</sub> | Z') as such a Functor.
```

σ Operator as Kan Extension

```
Let:
 D(A_{n-1} \mid Z) := Category of Morphic Chains over Z-frame Z
 D(B_{n-1} \mid Z') := Category of Morphic Chains over Z'-frame Z'
Define:
 \sigma_{safe} = Lan_{\sigma} : D(A_{n-1} \mid Z) >> D(B_{n-1} \mid Z')
such that:
For any object d \in D(B_{n-1} \mid Z'),
Lan_{\sigma} (D(A_{n-1} \mid Z))(d) := colim_{\{(c, f: \sigma(c) \rightarrow d)\}} D(A_{n-1} \mid Z)(c)
And:
For any morphism h: d \rightarrow d' in D(B_{n-1} \mid Z'),
Lan_σ (h) is defined to preserve functoriality
Lan \sigma (h) \circ Lan \sigma (f) = Lan \sigma (h \circ f)
Therefore:
σ safe satisfies:
  Object-level safe lifting: Ob(D(A_{n-1} \mid Z)) \rightarrow Ob(D(B_{n-1} \mid Z'))
  Morphism-level safe lifting: Mor(D(A_{n-1} \mid Z)) \rightarrow Mor(D(B_{n-1} \mid Z'))
σ_safe = Left Kan Extension guarantees the Quasi-Natural Transformation property
\forall f \in Mor(D(A<sub>n-1</sub> | Z)),
Lan_{\sigma} (G \circ f) = (Lan_{\sigma} G) \circ (Lan_{\sigma} f)
```

Relation to Qasi-Natural Transformation

The σ mapping operator, defined as a Functor σ : $D(A_{n-1} \mid Z) >> D(B_{n-1} \mid Z')$, exhibits structural alignment with Quasi-Natural Transformation (QNT) in the following way.

In the original formulation of QNT in this framework

```
\begin{array}{l} \eta \colon \, D_i \, \Rightarrow \, D_{i+1} \, \mid \, CD \, \, (\text{codomain}) \\ \\ \eta_{\_} X \, \circ \, D_i (\{f_1 \, \mid \, Z_1, \, \ldots, \, f_n \, \mid \, Z_n\}) \, \approx \, D_{i+1} (\{f'_1 \, \mid \, Z_1, \, \ldots, \, f'_n \, \mid \, Z_n\}) \, \circ \, \eta_{\_} Y \end{array}
```

Diagram:

The Quasi-Natural Transformation mediates conceptual flow correspondence across different morphic chain categories under a shared or shifted Z-frame.

In the Kan Extension formalization:

```
Lan_{\sigma} (D(A_{n-1} | Z)) = D(B_{n-1} | Z')
```

The lifting of the entire functor $D(A_{n-1} \mid Z)$ under σ corresponds to constructing a universal QNT from $D(A_{n-1} \mid Z)$ to $D(B_{n-1} \mid Z')$.

More precisely, for any object $d \in D(B_{n-1} \mid Z')$:

```
Lan\_\sigma \ (D(A_{n-1} \mid Z))(d) := colim\_\{(c, f: \sigma(c) \rightarrow d)\} \ D(A_{n-1} \mid Z)(c)
```

yields a canonical shifting from the conceptual flow space under Z to the corresponding conceptual flow space under Z', respecting the structural continuity required by QNT.

Thus:

```
\sigma_{-}safe \approx Left Kan Extension \approx Universal Quasi-Natural Transformation between D(A_{n-1}~|~Z) and D(B_{n-1}~|~Z')
```

Diagram:

This formalization guarantees that the Quasi-Natural Transformation property observed in the original Conceptual Cage structure is preserved and generalized through the Kan Extension framework, providing a categorical foundation for conceptual flow lifting.

1.4 Kan Extension as Horizontal Conceptual Shifting and Cone Structure

Conceptually, σ operator as Kan Extension performs not only lifting of morphic chains but also acts as a horizontal mapping across Z-frames, shifting conceptual flow from Fiber over Z to Fiber over Z'.

Diagrammatically, this can be visualized as a horizontal shift.

```
Fiber over Z (Mammal):

puppy → dog → mammal
girl → she → mammal

↓↓↓↓↓↓↓ Kan Extension σ(Life)

Fiber over Z' (Life):

girl → she → mammal → Life
puppy → dog → mammal → Life
```

Applying $\sigma(Life)$ results in a horizontal lifting of codomain alignment

Recursive Kan Extension as Iterated Colimit of Conceptual Shiftings

Conceptually, Recursive Kan Extension can be understood as constructing an iterated colimit of sequential conceptual shiftings (σ operators) across Z-frames.

Conceptual Ladder Structure:

```
Fiber over Z_0
\downarrow \sigma_1

Fiber over Z_1
\downarrow \sigma_2

Fiber over Z_2
\downarrow \sigma_3

Fiber over Z_3
\downarrow \dots

NL: turtle \rightarrow reptile \rightarrow animal \rightarrow \dots
```

Iterated Colimit Perspective:

At each stage, the application of σ_n corresponds to forming a conceptual projection from Fiber over Z_{n-1} to Fiber over Z_n .

The entire ladder:

```
Lan_{\sigma_n} \circ \ldots \circ Lan_{\sigma_3} \circ Lan_{\sigma_2} \circ Lan_{\sigma_1}
```

can be viewed formally as an iterated colimit over the sequence of Z-frames, forming a conceptual cone over the diagram.

```
colim_{Z_0} \rightarrow Z_1 \rightarrow Z_2 \rightarrow \dots \rightarrow Z_n \} (Lan_{G_i} (\pi^{-1}(Z_{i-1})))
```

Interpretation:

Each Lan_ $\{\sigma_i\}$ acts as a conceptual lifting operation, progressively shifting semantic flow across Z-frame layers. The cumulative structure forms an iterated conceptual cone, whose colimit aligns the entire sequence into the semantic flow space under Z_n .

Diagram (Iterated Colimit View):

```
Fiber over Z_0
\downarrow \sigma_1
Fiber over Z_1
\downarrow \sigma_2
Fiber over Z_2
\downarrow \sigma_3
Fiber over Z_3
\downarrow \dots
Iterated Colimit (Conceptual Cone)
\rightarrow \text{Fiber over } Z_n
NL: tortoise \rightarrow \text{ turtle } \rightarrow \text{ reptile } \rightarrow \text{ animal } \rightarrow \dots \mid \text{ Iterated Colimit Result } = \text{ Muti Celluar Organism}
```

Formal Expression:

```
Iterated\_Colimit = colim\_\{Z_0 \rightarrow Z_1 \rightarrow Z_2 \rightarrow \dots \rightarrow Z_n\} \ (Lan\_\{\sigma_i\}(\pi^{-1}(Z_{i-1})))
```

This conceptual ladder forms an iterated semantic cone, whose colimit aligns the entire Z-frame sequence into the unified semantic flow space under Z_n .

Diagram:

```

\downarrow
M|Z_n \text{ (colimit of Ladder)}
```

A cone on a diagram F: $J \to C$ is a universal natural transformation from a constant diagram ΔX to F. In this case:

```
\begin{split} &\Delta(\pi^{-1}(Z_n)) \ \Rightarrow \ \mathsf{Ladder} \ \mathsf{of} \ \mathsf{Lan}_{-}\{\sigma_i\}(\pi^{-1}(Z_{i-1})) \\ &\text{or as monoid structure} \\ &\mathsf{M}|Z_n \ \{ \ \mathsf{F}_n \ \circ \ \ldots \ \circ \ \mathsf{F}_1 \ | \ \mathsf{all} \ \mathsf{F}_i \colon \mathsf{F}_i \ \Rightarrow \ \mathsf{F}_{i+1} \ | \ \mathsf{Z}_n \ \land \ \forall \ i, \ j \colon \mathsf{F}_i \ \cong \ \mathsf{F}_j \ | \ \mathsf{Z}_n \ \} \end{split}
```

∞-Morphic Interpretation of Recusive Ken Extension

Viewed categorically, this recursive construction aligns with the notion of ∞ -morphisms or higher morphic flows, where each application of Lan_{ σ_i } corresponds to a morphism in an extended conceptual category, and their collective composition forms an ∞ -structured cone.

```
∞-Universal Product = colim_{Z_0 \rightarrow Z_1 \rightarrow Z_2 \rightarrow ... \rightarrow Z_n} (Lan_{\sigma_i}(\pi^{-1}(Z_{i-1})))
```

Diagram:

NL Diagram:

This interpretation enables the Conceptual Topos or Conceptual Topology to naturally support recursive, layered conceptual flow, where mappings can extend across arbitrarily many Z-frames while preserving structural coherence.

Example: Iterated Kan Extension of Conceptual Ladder

Step 1:

```
Z_0 = Turtle Z_1 = Reptile \sigma_1 = \sigma(\text{Reptile}): Turtle \to Reptile \sigma_1 = \sigma(\text{Reptile}): Turtle \to Fiber over Reptile
```

Step 2:

```
Z_2 = Animal \sigma_2 = \sigma(\text{Animal}) \colon \text{Reptile} \to \text{Animal} \text{Lan}_{\sigma_2}(\pi^{-1}(\text{Reptile})) \to \pi^{-1}(\text{Animal})
```

Step 3:

```
Z_3 = Life \sigma_3 = \sigma(\text{Life}): Animal \rightarrow Life  \text{Lan}_{\sigma_3}(\text{Fiber over }\pi^{-1}(\text{Animal})) \rightarrow \pi^{-1}(\text{Life})
```

Composition:

```
Lan_{\sigma_3} \circ Lan_{\sigma_2} \circ Lan_{\sigma_1}(\pi^{-1}(Turtle))
```

Colimit:

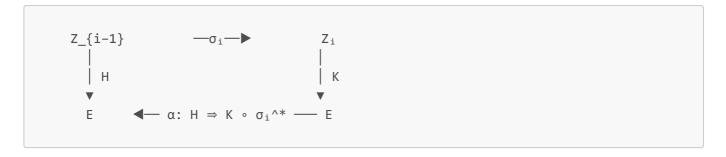

```
colim_{Z_0} \to Z_1 \to Z_2 \to Z_3 Lan_{G_1}(\pi^{-1}(Z_{i-1})) = \pi^{-1}(Z_3) = \pi^{-1}(Life)
```

NL:

```
Turtle → Reptile → Animal → Life
```

Conceptual flow lifted across Z-frame layers as iterated Kan Extensions, converging to the unified flow under Life.

Universal Property of Lan_ $\{\sigma_i\}$

```
Given a base conceptual shifting operator
\sigma_i: Z_{i-1} >> Z_i
we define Lan_{\{\sigma_i\}} for corresponding fiber categories
Lan_{\sigma_i} : \pi^{-1}(Z_{i-1}) \to \pi^{-1}(Z_i)
To satisfy the following **universal property**, for any functor
H: \pi^{-1}(Z_{i-1}) \to E
and any functor
K: \pi^{-1}(Z_i) \rightarrow E
with a natural transformation
\alpha: H \Rightarrow K \circ \sigma_i^*
(where \sigma_i^* is the pullback functor along \sigma_i),
there exists a unique natural transformation
\beta: Lan_{\sigma_i}(H) \Rightarrow K
such that the following diagram commutes
Н
↓ α
K \, \circ \, \sigma_{\mathtt{i}} \, {}^{\wedge *}
1
Lan_{\sigma_i}(H) \circ \sigma_i^*
In formal terms
Nat(H, K \circ \sigma_{i}^{*}) \cong Nat(Lan_{\sigma_{i}}(H), K)
```

NL Diagram: The operation smartphone → GPS maintains the structural coherence under Gadget when lifting it to Instrument.

NL Example 2

```
A functor F: Canine → Life
A functor σ: Canine → Mammal
Then the left Kan extension of F along \sigma is a functor.
Lan_{\sigma}(F): Mammal \rightarrow Life
Object d \in Mammal, c \in Canine, d,c \in Life
Lan_{\sigma}(F)(d) = colimit (\sigma(c) \rightarrow d)(F(c))
  Canine —
                              ─ Mammal
                              \sigma(fox), \sigma(dog), cat
   fox, dog
         F
                                       Lan_{\sigma}(F)
                                   - Life
   Life ◀-
               dog → cat
e.g. Lan_\sigma(f)(fox) = dog \rightarrow cat
fox, dog, cat ∈ Life
fox, dog, cat ∈ Mammal
fox, dog ∈ Canine
We focus on fox.
fox ∈ Canine
                                        // fox is a canine
F(fox) = dog \in Life
                                       // fox behaves like dog in the context of Life
\sigma(\text{fox}) \colon= \text{dog} \to \text{cat} \mid \text{Mammal} \qquad // \text{ Under Mammal, fox is like a dog or a cat, not}
a gorilla. (QNT)
dog → cat | Mammal
                                      // dogs, as mammals, resemble cats.
```

```
⇒ Lan_σ(F)(fox) = dog → cat | Life
That is:
    A fox, seen as a canine, is mapped to a dog under the functor: Canine → Life,
    But as mammals, dogs resemble cats,
    The fox is, in Life, conceptually equivalent to a transition, dog → cat − that
is, the fox is basically dog or cat.

Note:
    The transition (dog → cat | Life) is interpreted as a Quasi-Natural
Transformation (QNT):

    ↑: dog ⇒ cat | Mammal
    dog → Life ∘ η_Y ≈ η_X ∘ cat → Life
    NL: "Cat is a dog, and dog is a cat − basically, under the Life frame."
```

Example:

```
f₁: king → man
                             | Z<sub>1</sub>
f_2: woman \rightarrow ?
                             | Z<sub>1</sub>
Conceptual Shifting Operator
\sigma_1: Z_1 \gg Z_2 (GenderedEntity \gg SocialRole: Generalization)
\sigma_2: Z_3 << Z_2 (SocialRole << RoyalSemantic: Specification)
Lan_{\sigma_1}(f_1): king \rightarrow male-role \mid Z_2
Lan_{\sigma_1}(f_2): female-role \rightarrow female-role \mid Z_2
Lan \{\sigma_2\} (Lan \{\sigma_1\} (\{f_1\}): king \} king |Z_3|
Lan_{\sigma_2}(Lan_{\sigma_1}(f_2)): queen \rightarrow queen Z_3
We may define \sigma_3 = \sigma_2 \circ \sigma_1 : Z_1 \rightarrow Z_3 as the composition of generalization and
specification,
allowing us to write Lan_{\sigma_3}(f) \cong Lan_{\sigma_2}(Lan_{\sigma_1}(f))
Alternately, We define the above as fibers.
\pi^{-1}(Z_1): Gendered Entity
\pi^{-1}(Z_2): Social Role
\pi^{-1}(Z_3): Royal Semantic
colim_{Z_1} \rightarrow Z_2 \rightarrow Z_3 (Lan_{\sigma_i}(\pi^{-1}(Z_i)))
\thereforeLan_{\sigma_2}(Lan_{\sigma_1}(king - man + woman)) \cong queen
```

Diagram:

```
Z<sub>1</sub>: Gendered Entity
  king → man
  woman

σ<sub>1</sub> ↓ Generalized to Social Role

Z<sub>2</sub>: Social Role
  king → male-role
  female-role → female-role

σ<sub>2</sub> ↓ Specified to Royality

Z<sub>3</sub>: Royal Semantic
  king → king
  queen → queen
```

Iterated Kan Extension Ladder over the Z-frame

```
Z_0 \rightarrow Z_1 \rightarrow Z_2 \rightarrow \dots \rightarrow Z_n
\pi^{-1}(Z_0) \rightarrow \pi^{-1}(Z_1) \rightarrow \pi^{-1}(Z_2) \rightarrow \dots \rightarrow \pi^{-1}(Z_n)
Lan_{\sigma_n} \circ \dots \circ Lan_{\sigma_1}(\pi^{-1}(Z_0)) \rightarrow \pi^{-1}(Z_n)
```

Iterated colimit approximates the unified conceptual flow

```
Iterated\_Colimit \cong colim\_\{Z_0 \rightarrow Z_1 \rightarrow \dots \rightarrow Z_n\} \ (Lan\_\{\sigma_i\}(\pi^{-1}(Z\_\{i-1\})))
```

Example: Pullback of a Meaning Transformation via σ₁^

We consider a morphism in the fiber over Z_2 = Instrument

```
f: smartphone → GPS | Z<sub>2</sub>
```

Let $\sigma_1: Z_1 \to Z_2$ be a contextual shift from $Z_1 = Gadget$ to $Z_2 = Instrument$. To interpret this transformation from the perspective of Z_1 , we apply the pullback functor $\sigma_1^{\wedge *}$.

This yields

```
\sigma_1^*(f): smartphone \rightarrow smartphone-GPS | Z_1
```

where smartphone-GPS is a more concrete or reduced interpretation of GPS within the limited frame of Z₁.

Diagram:

Safe / Unsafe Conceptual Shifting Morphism (σ)

Definition of Safe and Unsafe σ Operator

Conceptual Shifting Morphism (σ) can be classified based on whether it preserves the global coherence of the morphic chain.

Safe σ **Operator** (σ _safe) Acts on the entire morphic chain as a coherent transformation.

```
\sigma_{\tt}safe \colon \, D(A_{n-1} \mid Z) \, > \, D(B_{n-1} \mid Z') \mid Z >> \, Z' \, \lor \, Z << \, Z' where: Z, Z' \in CD
```

Behaves as a Quasi-Natural Transformation

```
\sigma_{safe} = \eta: D_i \Rightarrow D_{i+1} \mid CD
```

Composition is associative:

```
(\sigma_3 \circ \sigma_2) \circ \sigma_1 = \sigma_3 \circ (\sigma_2 \circ \sigma_1)
```

Resulting chain remains in M|Z or $M_{Z'}$ (closed).

Example

```
\sigma_1(X). >(canine, mammal)

\sigma_2(X). >(mammal, animal)

\sigma_3(X). >(animal, livingBeing)

Composition:

(\sigma_3 \circ \sigma_2) \circ \sigma_1 = \sigma_3 \circ (\sigma_2 \circ \sigma_1)

\rightarrow >(canine, livingBeing)

Entire morphic chain is preserved.
```

Unsafe σ Operator (σ _unsafe) Does not preserve global coherence of the morphic chain. Acts locally or in a decomposed manner.

Chain may collapse:

```
\sigma_{unsafe}: D(A<sub>n-1</sub> | Z) → { rupture(f<sub>1</sub>), rupture(f<sub>2</sub>), ..., rupture(f<sub>n</sub>) | ¬Z }
```

```
rupture(f, \sigma(f) \mid Z) \neq \emptyset
```

Cannot be captured by a Quasi-Natural Transformation globally.

Example

```
\sigma(X). Not(x) { A \rightarrow/B | Z }

Result:
rupture(A \rightarrow/B | Z)
\rightarrow breaks the morphic flow \rightarrow chain decomposes.
```

2. Monoid Structure of Conceptual Flow (M|Z):

In Conceptual Topology, Z is defined as a mediating point/conceptual anchor.

```
Let C and D, Z be categories,
with conceptual projection \pi: C \cup D \rightarrow Z, such that for each X \in Ob(C \cup D)
\pi(X) \in Ob(Z)
For each X \in Ob(C \cup D), there exists morphism
f_X: X \to \pi(X)
f_X^{-1}: \pi(X) \rightarrow X
such that
f X^{-1} \circ f X \cong id X
For morphism f: X \rightarrow Y \mid Z,
this corresponds to:
f_Z: \pi(X) \rightarrow \pi(Y) \mid Z
For any X, Y \in Ob(C \cup D)
Let [X]_Z := conceptual representation of X under frame Z (i.e., <math>\pi(X))
Then:
[ X ]_Z1 \cong [ Y ]_Z2 | Z1, Z2 \in Z //or Z1, Z2 \Rightarrow Z
which means
["Dog"]_Pet = [Retriever, Dachshund, Poodle, Bulldog, ...]
["girl"]_Human = [girl, woman, person, ...]
["Dog"]_Pet ≅ ["girl"]_Human | Life
Then the set of conceptual flow morphisms under Z forms a monoid
M|Z = \{ f_n \circ \ldots \circ f_1 \mid all f_i \colon X_i \to X_{i+1} \mid Z \land \forall i, j \colon f_i \cong f_j \mid Z \}
This is also defined as Morphic Chain.
Let D(C_{n-1} \mid Z) := Category of Morphic Chains over Ob(C_{n-1}) within a given Z-frame.
where: D(C_{n-1} \mid Z) = \{ C_0 \rightarrow C_1 \rightarrow C_2 \rightarrow ... \mid Z \}
or as a set
D(C_{n-1} \mid Z) = \{ C_0, C_1, C_2, ... \mid Z \}
```

3. Identity Element of M|Z

```
Let: M|Z = \{ f_n \circ \ldots \circ f_1 \mid \text{all } f_i \colon X_i \to X_{i+1} \mid Z \land \forall i, j \colon f_i \cong f_j \mid Z \}
Define the identity element of M|Z as a family of identity morphisms over the shared Z frame:

For each X \in Ob(C \cup D), there exists a unique identity morphism under a Z frame:
e|Z\_X := id\_X \mid Z
Then, for any f \colon X \to Y \mid Z \in M|Z:
e|Z\_X \circ f = f
f \circ e|Z\_Y = f
Therefore, the identity structure of M|Z is given by the family:
\{ id\_X \mid Z \mid X \in Ob(C \cup D) \}
which forms a pointwise identity across the objects under the common Z frame. This ensures that M|Z satisfies the identity axiom of a monoid.
```

4. Associativity of M | Z

```
Let: M|Z=\{f_n\circ\ldots\circ f_1\mid all\ f_i\colon X_i\to X_{i+1}\mid Z\wedge\forall\ i,\ j\colon f_i\cong f_j\mid Z\} Then for all f, g, h \in M|Z: (f\circ g)\circ h=f\circ (g\circ h) Thus, the composition \circ in M|Z is associative.
```

5. Axioms

5.1. Identity Element

Unit Axiom 1: Identity Element Z

```
id_Z:=Z \rightarrow Z \mid Z

\forall f \in MIZ: id_Z \circ f = f and f \circ id_Z =
```

Definition:

```
Statement:
Z-frame itself is the unit of M \mid Z.
Formal Definition:
Z := Z \rightarrow Z|Z
Justification:
Since any morphism in M | Z is defined as:
f: X→YIZ
and Z itself is defined as its own identity morphism:
Z := Z \rightarrow Z \mid Z
then:
id_Z = Z
Conclusion:
Therefore:
id_Z is the unit element of MIZ.
\forall f \in MIZ: (id_Z \circ f \mid Z) = f \text{ and } (f \circ id_Z \mid Z) = f
(with frame-preserving composition)
∴id_Z is the unit of MIZ.
```

Note:

```
idZ :Z→Z | Z
f:X→Y | Z
(idZ|Z)∘(X→Y|Z)
```

Unit Axiom2: Void Concept

```
f \in M|Z
"" \circ f = f and f \circ "" = f
id_Z \circ f = f and f \circ id_Z = f
```

Definition:

```
The empty concept is a theoretically assumed concept, denoted as "", which acts as the unit element at the conceptual / lexical level.

Formal Definition:

"" o f = f and f o "" = f

Justification:

The empty concept "" represents no lexical or conceptual content.

Composing any morphism f with the empty concept does not alter the flow of meaning.

Conclusion:

"" is the unit element at the conceptual level of Conceptual Topology.
```

5.2. Zero Morphism: Negation Morphism

We define conceptual zero morphism, negation morphism: n_f In CT as the result of applying Not() to a morphism

```
g:\sigma(Z). Not(g){ A \rightarrow/B | Z} = A \rightarrow/B|Z = n_f where: g: A \rightarrow B

Formal Properties (Axiom):

\forall g: X \rightarrow Y \mid Z where composition with n_f is defined:

\forall g: g \circ n_f = n_f \text{ and } n_f \circ g = n_f

Left Side:
g: A \rightarrow B
g \circ (A \rightarrow B \mid Z) = A \rightarrow A \cap B \mid Z

Right Side
g: A \rightarrow B \circ (A \rightarrow B \mid Z) \circ g = A \rightarrow B \mid Z
```

```
Interpretation:
Applying Not() to any morphism produces a conceptual zero morphism, which
collapses any further conceptual flow.
```

NL Diagram:

Natural Language:

```
Left Side: g∘(A→β|Z)

"A is not B"

The apple is not a fruit

Right Side: (A→β|Z)∘g

"B is not A"

This is a fruit, but this is not an apple which is a fruit.

In CT, this was called rutpure().

Now defined:

rupture(A,B,Z)= σ(Z).Not(g) = n_f = A→β|Z
```

5.3. Composition Axiom

Example:

```
For f, g, h ∈ M|Z,
```

```
where:
f: she \rightarrow you \mid Human
g: he \rightarrow she \mid Human
h: man \rightarrow he \mid Human
(f \circ g) \circ h = f \circ (g \circ h)
```

6. Conceptual Topos

6.1. Category Level: Initial Object

Definition:

```
Let Concept be a category where Ob(Concept) are lexical / conceptual objects. Then "" \in Ob(Concept) is Initial Object if:

\forall \ X \in \text{Ob}(\text{Concept}), \ \exists \ \text{unique morphism:}
u_X : \text{""} \rightarrow X \mid X
\text{such that:}
\forall \ f: \ X \rightarrow Y \mid Z,
f \circ u_X = u_Y
```

Monoid Level: Unit in M|Z

```
Recall:  M|Z = \{ \ f_n \circ \ldots \circ f_1 \ | \ all \ f_i \colon X_i \to X_{i+1} \ | \ Z \wedge \ \forall \ i, \ j \colon f_i \cong f_j \ | \ Z \ \}   Now, define:  "" \in Ob(Concept)  and identity morphism under Z-frame:  e|Z\_"" \ := \ id\_"" \ | \ Z  Then for all f \in M|Z:  e|Z\_"" \circ f = f   f \circ e|Z\_"" = f
```

6.2. Finite Limits

Terminal Object Conceptual Topos defines a terminal object as the Z-frame identity:

```
id_Z := Z \rightarrow Z \mid Z Any morphism f: X \rightarrow Z \mid Z factors uniquely through id_Z. This realizes the conceptual universal target: \forall \ X \in Ob(C \cup D), \ \exists! \ f\_terminal: \ X \rightarrow Z \mid Z
```

Example:

```
she → human
me → human | Human
```

Pullback

This previously defined as Quasi-Natural Transformation:

```
\eta: D_i \Rightarrow D_{i+1} \mid CD (CD = codomain)
\eta_{\_}X \, \circ \, D_{\mathtt{i}}(\{f_{\mathtt{1}} \ | \ Z_{\mathtt{1}}, \ \ldots, \ f_{\mathtt{n}} \ | \ Z_{\mathtt{n}}\}) \, \approx \, D_{\mathtt{i}+\mathtt{1}}(\{f'_{\mathtt{1}} \ | \ Z_{\mathtt{1}}, \ \ldots, \ f'_{\mathtt{n}} \ | \ Z_{\mathtt{n}}\}) \, \circ \, \eta_{\_}Y \, \mid \, \mathsf{CD}
for all f_j: X_j \rightarrow Y_j \mid Z_j \in D_i,
where f'_j: \eta_X(X_j) \rightarrow \eta_Y(Y_j) \mid Z_j
Then, \eta is said to be a quasi-natural transformation under the Z-frame
i.e. \eta \in Mor(C) where C is the contextual meaning category
\eta_X \circ D_i(\{girl \rightarrow mammal \mid Z_1\}) \approx D_{i+1}(\{puppy \rightarrow mammal \mid Z_2\}) \circ \eta_Y
Pullback Diagram
         Mammal
girl
                    puppy
       Baby (conceptual anchor / common Z-frame)
Example: \eta: girl \rightarrow puppy | Z = Baby
Quasi-Natural Transformation Diagram:
            Z = baby
      puppy ← girl
                                  //specified: size + young
                       she
                                   //abstraction
      dog
            Mammal
For any X with morphisms
q_1: X \rightarrow girl \ and \ q_2: X \rightarrow puppy \ satisfying f \circ q_1 = g \circ q_2,
there exists unique u: X → Baby
such that:
p_1 \circ u = q_1, p_2 \circ u = q_2.
```

Equalizer: Mirror Morphism

In conceptual topology this was defined as mirror morphism:

```
\begin{array}{lll} f: X \rightarrow Y & \mid Z \in D_i \\ f': X' \rightarrow Y' & \mid Z \in D_{i+1} \\ \rightarrow X' \neq X, \text{ but } cod(f) = cod(f') & \mid CD \text{ ( common codomain)} \\ \\ \text{We define } f' \text{ as a mirror-correspondent morphism of } f \text{ under a given } Z\text{-frame,} \\ \text{if and only if:} \\ \\ \exists Z: \text{ rupture}(f, f' \mid Z) \neq \emptyset \\ \land \text{ cod}(f) = \text{cod}(f') & \mid CD \\ \\ & Eq(f, f') \\ & \mid & \\ & e \\ & v \\ \\ X & X' \\ & \setminus & / \\ & \setminus & / \\ & \vee & V \\ & Y = Y' \text{ (codomain = C)} \\ \end{array}
```

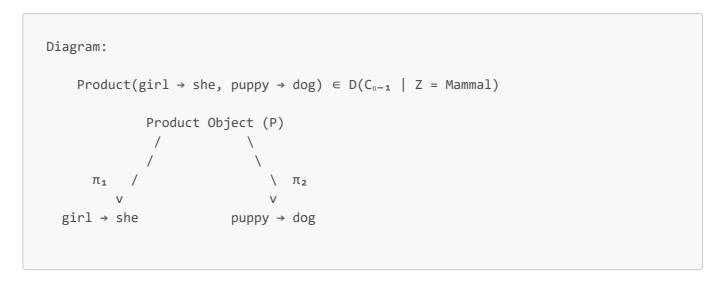

Product: σ operator⊕

```
In any category C, the Product of A and B is an object A \times B equipped with projections:  \pi_1 \colon A \times B \to A \\ \pi_2 \colon A \times B \to B  with universal property: For any object X with morphisms:  f_1 \colon X \to A \\ f_2 \colon X \to B  there exists a unique morphism u \colon X \to A \times B such that:  \pi_1 \circ u = f_1 \\ \pi_2 \circ u = f_2
```

Addition (⊕):

 $\sigma(Z)$ serves as the mediating operator ensuring that the composed morphic chain remains within the conceptual fiber over Z.

```
Defined as: \sigma(Z). \ \oplus (A_{n-1}, \ B_{n-1}, \ Z) = D(C_{n-1} \ | \ CD) = M_C \ | \ CD Example: A_{n-1} := girl \to she \ | \ Human B_{n-1} := puppy \to dog \ | \ Canine \sigma(Human). \ \oplus (girl \to she, \ puppy \to dog \ | \ Mammal) \to M \ | \ Z(girl \to she \to puppy \to dog \ | \ Mammal) \to Composite \ meaning \ space
```

6.3. Exponentials

Conceptual Topos models exponentials via conceptual shift operators.

Definition

```
For any objects A, B: B^A \text{ exists such that:} \\ Hom(X \otimes A, B) \cong Hom(X, B^A)
```

Construction via σ operator

Conceptual shift operators:

```
\sigma(Z). >> (A, B) or \sigma(Z). >(A, B) act as internal exponential morphisms within the fibered structure over the Z-frame: (A, B, Z) \cong B^A where the Z-frame mediates the conceptual continuity and contextual grounding of the morphic shift.
```

We define Exponential objects via σ operator as conceptual abstraction mechanisms:

```
B^A:=σ(Z).>(A,B)
```

Exponentials as If: Conditional Statement

In NL Diagram:

We formalize this as eval function in CTL(Conceptual Topology Language). We employ programing style to track dynamic transformation of conceptual flow.

```
def exponential(a: Concept, b: Concept, z: Frame) -> ConceptualMorphism::
    """
    Construct exponential object B^A under Z-frame.
    Represents: 'if a then b' interpreted within context c.
    """
    return σ(z).>(a, b) // represents B^A

def eval(f: Conceptual Morphism, a: Concept, z: Frame) → Concept:
    return f × a | z

Example:
    //if press then open → it opens
    eval("press", "open", "door") → door → opened door | Door
```

```
//if press then open + you press → it opens
f = exponential("press", "open", "door")
eval(f, "you press") → open | Door
```

Full Exponential Law formalization will be provided in later version.

Definition: Conceptual Shifting Morphism (σ)

```
\sigma: D(X<sub>n-1</sub> | X) → D(X<sub>n-1</sub> | X)

such that \sigma \oplus f \in M|Z if and only if type compatibility holds:

\forall A, B, (A \to B) \circ \sigma(X) is valid if:

(A \to X \text{ or } X \to A)
and
(B \to X \text{ or } X \to B)

Definition: Subsumption
A \to X \equiv A \equiv X

Definition: SubsumedBy
X \to A \equiv X \subseteq A

Example:
king \to king \to human \to human
\Rightarrow king \to human \to valid

human \to human \to queen \to queen
\Rightarrow human \to queen \to queen \to queen
```

Example

```
σ(Human). >>(puppy → dog → mammal | Canine, Human)
≅ girl → she → mammal | Human
```

This shift realizes an internal conceptual transformation corresponding to exponential behavior.

6.4. Definition of Ω

Let Ω be an object in the Concept category, representing the **conceptual truth space**.

```
For any subobject (conceptual inclusion):
```

 $m: M \hookrightarrow X$

there exists a unique characteristic morphism:

 $\chi_m: X \to \Omega$

such that the following diagram commutes:

Interpretation in Conceptual Topology

- Ω encodes conceptual entailment / membership / inclusion.
- **Z-frame membership** is naturally mapped to Ω :

$$\chi_Z: X \to \Omega$$

interpreted as:

"Does X conceptually belong to Z-frame Z?"

Examples

Example 1: Dog in Pet Z-frame

 $\chi_{\text{Pet}}(\text{Dog}) = \text{True}$

Example 2: Apple in Pet Z-frame

 χ _Pet(Apple) = False

Example 3: Innocent in Body Z-frame (after rupture)

 χ _Body("innocent") = True / False depending on whether the conceptual projection is coherent under Z-Frame.

Relation to Rupture

Conceptual rupture can be lifted to Ω as:

$$\sigma(Z)$$
. Not(f: A \rightarrow B | Z) \Rightarrow rupture(A,B,Z) \Rightarrow χ _Z(f) = False

Thus, negation and conceptual discontinuity become Ω -classifiable.

6.5. Conceptual Topos as Fibered Topos over Z-frame

Conceptual Topos is structured as a **fibered topos** over the conceptual base space **Z-frame**.

Z-frame as Fibered Structure

- Let π : $C \cup D \rightarrow Z$ be the conceptual projection.
- Each fiber $\pi^{-1}(Z)$ forms a category of morphic chains $\mathbf{D}(\mathbf{C_{n-1}} \mid \mathbf{Z})$.
- Morphisms of the form:

```
X \rightarrow Y \mid Z \equiv X \rightarrow Y \text{ in fiber over } Z
```

correspond to morphisms within the fibered structure over Z.

Initial Object and Codomain Projection

- The **Initial Object** "" serves as the conceptual origin.
- It projects into the codomain via:

```
"" \rightarrow | X \equiv "" \rightarrow \pi(X)
```

```
\begin{array}{c} \text{""} \\ \downarrow \text{ u\_X} \\ \text{X} & \longrightarrow \pi(\text{X}) \text{ (in Z-frame)} \end{array}
```

```
Fiber \pi^{-1}(Z_X):
"" \rightarrow X \rightarrow Y
```

Thus, conceptual generation naturally occurs anchored in Z-frame.

Conceptual Flow Closure

• Conceptual flows:

$$X \rightarrow Y \mid Z$$

are closed within the fiber over Z, corresponding to the codomain Z of the conceptual projection π .

• Rupture and negation are classified by Ω :

$$\chi_Z: X \to \Omega$$

7. Global Conceptual Space: Total Conceptual Space (TCS)

We define the Total Conceptual Space (TCS) as the global conceptual anchor:

```
Z = TCS = Total Conceptual Space
```

Definition of MITCS:

The global morphic flow space under TCS is defined as:

```
M|TCS = \{ f_n \circ \ldots \circ f_1 \mid all \ f_i \colon \ M|Z_i \rightarrow \ M|Z_{i+1} \mid TCS \ \land \ \forall \ i, \ j \colon f_i \cong f_j \mid TCS \ \}
```

We can regard M|TCS as the composition space of conceptual perspectives: Here, each M|Z functions as a conceptual symbolization or perspective lens, and M|TCS represents global flows across chained perspectives.

Monoid Closure Property:

```
Composition in M|TCS is closed:  \forall \ f, \ g \in M|TCS, \ f \circ g \in M|TCS  The identity morphism is preserved:  \forall \ f \in M|TCS, \ f \circ id = f = id \circ f
```

Thus, M|TCS forms a closed monoid under composition.

Completeness Statement:

```
For any pair of concepts X, Y: \forall \ X, \ Y \in Ob(C), \ \exists \ f \in Mor(C), \ such \ that \ f \colon X \to Y \ | \ TCS
```

That is, any conceptual pair X and Y can be connected via a morphic flow under TCS.

Fibered Structure and Lifting

Each local M|Z can be lifted into M I TCS via conceptual shifting σ :

```
∀MIZ, ∃σ: MIZ > MIZ | TCS
```

Thus, the global base space TCSTCSTCS ensures that the entire morphic flow space is both complete and coherent.

Example:

```
can → person | TCS
  → Metaphoric reading: "The can represents the absent person."
  → Ironic reading: "We are all cans under capitalism."
```

Summary:

The Total Conceptual Space (TCS) functions as the global base space of the conceptual topology. All local Z-frames are fibered over TCS, and conceptual flows can be lifted via σ operators into M | TCS. Thus, Conceptual Topos is complete and globally coherent under M | TCS.

8. Empirical Data for Conceptual Topology

8.1. Conceptual Flow Classification

We tested this framework, Conceptual Topology, using Principal Component Analysis(PCA).

First, we define the core conceptual flow diagram, interpreting Z as a retractive flow.

For reference: In the composition $A \to Z \to B$, the mediating Z can be interpreted as the distance between A and B. We define this as Z = ||A - B||, and denote the norm as ||Z||. In retraction $A \to Z \to A$ also behaves as a conceptual identity or coherent transformation via cosine similarity hinged on Z when Z is scalarized as ||Z|| under PCA projection.

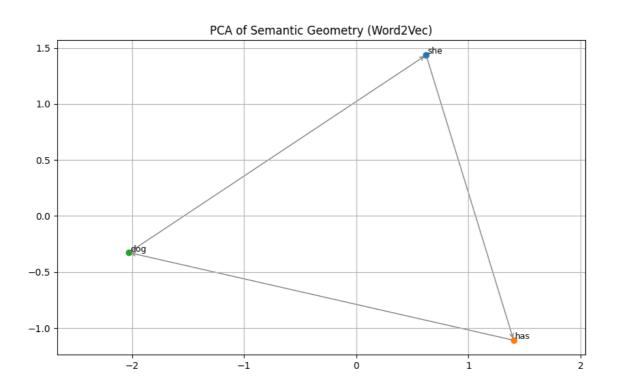

```
Alternatively, to express conceptual flow under Z f: A \rightarrow Z g: Z \rightarrow B such that g \circ f \cong A \rightarrow B | Z
```

We categorize flow structures based on the type of morphism.

Self Identity Morphism: Triangle

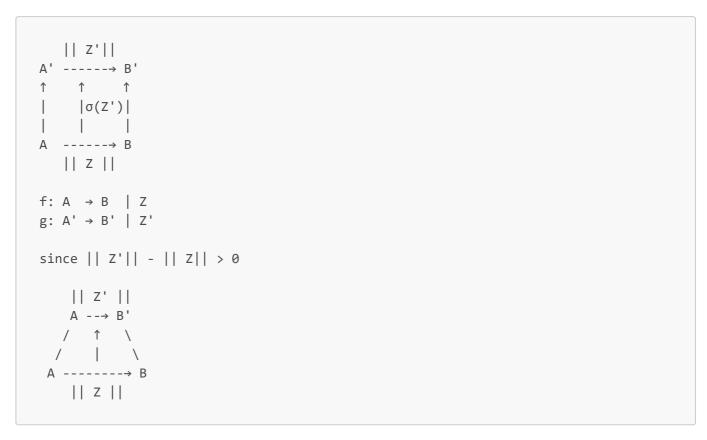

```
|| z'||
z' \longrightarrow z'
\uparrow \uparrow \uparrow \uparrow
| \sigma(z')|
| \mid | | \downarrow
A \longrightarrow B
|| z \mid | = 0
z'
\uparrow \uparrow
/ \mid \downarrow
A \longrightarrow B
|| z \mid |
```

She has a dog

While multiple interpretations are possible, this diagram offers the most coherent explanation. The morphism σ (possession) unifies she and dog under the relation of ownership: the owner and the owned.

Trapezoid

king, man , woman, queen

The trapezoid structure observed in king, man, woman, and queen can be interpreted as preserving the same major Z-axis—in this case, gender. Note: Z may also represent a multi-dimensional conceptual frame.

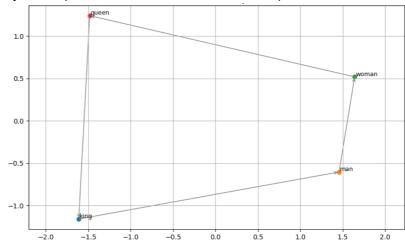

```
r
Q ← W

| f | h

| K W M
g

K = king
Q = queen
M = man
W = woman

g: Differential Morphism (King → Man)
h: Differential Morphism (Man → Woman)
r: Differential Morphism (Woman → Queen)
f: Composed Semantic Morphism r ∘ h ∘ g
```

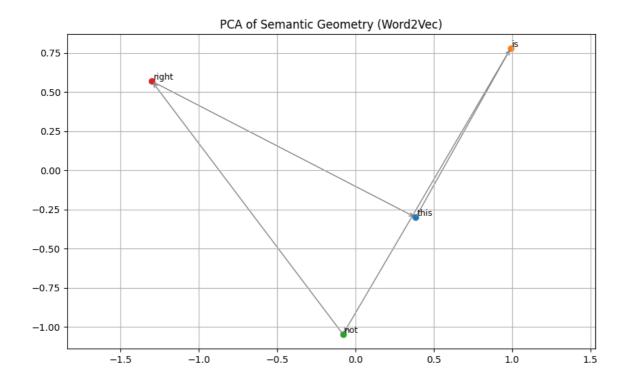

Rectangle

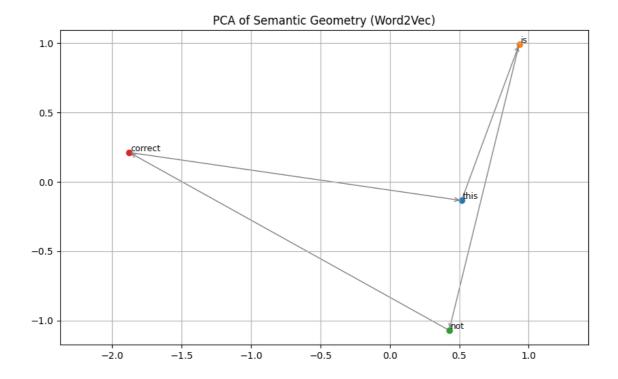

Rectangular structure signifies that Z and Z' is equivalent. This structural alignment suggests that the conceptual flow preserves its semantic frame, without requiring a shift in Z. Although the rectangular structure —corresponding to morphism preserving the conceptual frame Z—has not yet been observed in PCA projections, it remains a theoretically valid configuration. Detecting such a structure would signify complete semantic coherence between source and target morphisms.

8.2. Zero Morphism

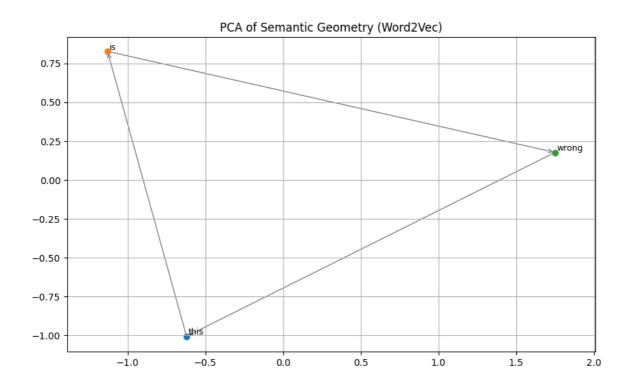

NL Diagram:

From the above formula, is was expelled from commutative structure and *not* replaced is completed conceptual circulation.

If a lexicon A which satisfy with *not* $B \subseteq A$ such as *wrong* can recover the conceptual flow.

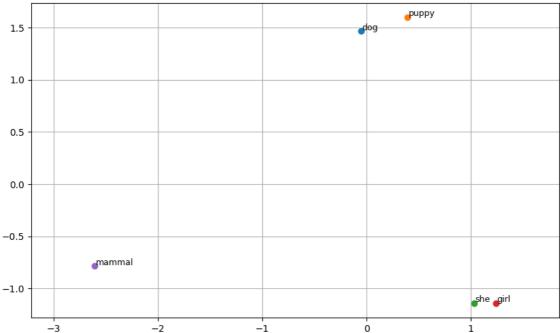

8.3. Cone Structre: Kan Extension and QNT

We can observe iterated colimit and QNT in PCA.

```
\begin{array}{lll} D_i = & colim_{puppy} \rightarrow & dog \rightarrow & mammal \} & (Lan_{\sigma_i})(\pi^{-1}(Mammal))) \\ D_{i+1} = & colim_{girl} \rightarrow & she \rightarrow & mammal \} & (Lan_{\sigma_i})(\pi^{-1}(Mammal))) \\ \\ & Here & Defined & QNT & Between & D_i & and & D_{i+1} \\ & \eta: & D_i \Rightarrow & D_{i+1} & | & CD = & Mammal \\ & \eta: & D_i & (\{f_1 \mid Z_1, \ldots, f_n \mid Z_n\}) \approx & D_{i+1}(\{f'_1 \mid Z_1, \ldots, f'_n \mid Z_n\}) \circ & \eta\_Y \mid CD \\ & for & all & f_j: & X_j \rightarrow Y_j & | & Z_j \in D_i, \\ & where & f'_j: & \eta\_X(X_j) \rightarrow \eta\_Y(Y_j) & | & Z_j \\ \\ & Then, & \eta & is & said & to & be & a & quasi-natural & transformation & under & the & Z-frame \\ & i.e. & \eta \in & Mor(C) & where & C & is & the & contextual & meaning & category \\ & Example: & \eta: & girl \rightarrow & puppy & | & Z & = & Baby \\ \end{array}
```

8.4. Universal Product

We did not define universal product in the above sections, yet this is observable in PCA.

```
Let C be a category and let A,B ∈Ob(C) be objects.

A product of A and B is an object P∈Ob(C) together with morphisms π_A:P → A

such that for any object X∈Ob(C) with morphisms f:X→A, g:X→B

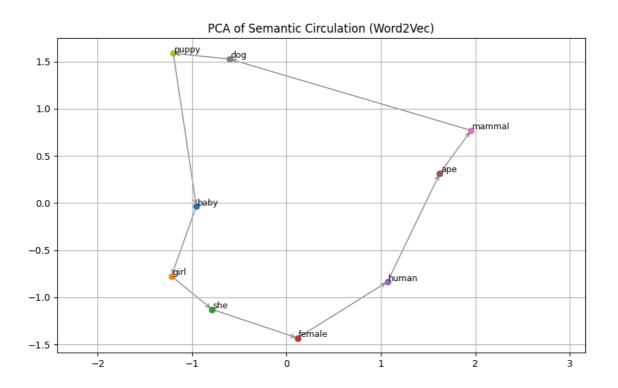

there exists a unique morphism ⟨f,g⟩
    X→P

such that the following diagram commutes π_A∘(f,g)=f, π_B∘(f,g)=g

Mammal

/ \
/ \
/ \
/ \
/ \
V P = Baby V

Puppy <-- P --> Girl
π_A π_B
```

8.5 Computational Methodology to induce Z-frame

A Z-frame acts as a cone shape in morphic structure—its role is to anchor multiple conceptual flows into a unifying conceptual topology. In category-theoretic terms, the Z-frame corresponds to the colimit of a diagram.

While colimits are traditionally defined via universal properties over cones, in natural language processing (NLP), a colimit can be approximated by KMeans clustering over word embeddings. If we interpret a cone from the side, we observe its tapering morphic shape; but from above, the apex of the cone corresponds to the conceptual anchor (Z-frame) toward which all points converge.

Z frame: king, queen, man woman

Using a simple KMeans (k=1) over these four word vectors yields the following cluster center and its top 10 closest neighbors.

```
=== Z-frame Candidates ===

queen : Similarity = 0.7720

woman : Similarity = 0.7235

king : Similarity = 0.7221

man : Similarity = 0.6933

princess : Similarity = 0.6631

girl : Similarity = 0.6182

monarch : Similarity = 0.6139

prince : Similarity = 0.6070

lady : Similarity = 0.5850

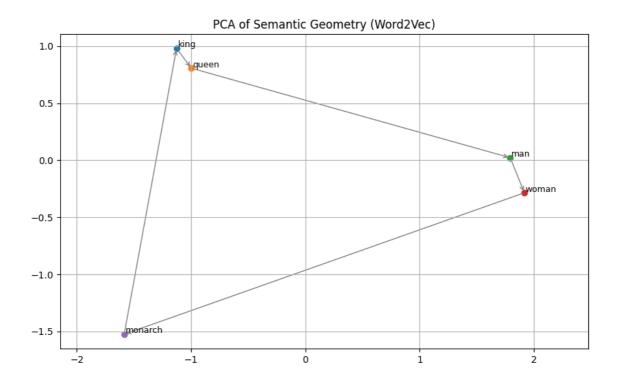

teenage_girl : Similarity = 0.5712
```

Remarkably, monarch emerges from a purely geometric computation. This term does not merely appear due to proximity in vector space, but because it semantically subsumes king, queen, man, and woman in terms of parochial authority. Thus, monarch behaves as a Z-frame, mediating the entire morphic configuration.

Diagram:

PCA Interpretation

Although the PCA projection did not produce a perfectly symmetric cone structure, we can semantically interpret this as reflecting the historical structure of patriarchal monarchy.

In this frame, the transformation from king \rightarrow queen or man \rightarrow woman does not converge straight onto the concept monarch as we saw in puppy to dog and girl to she. This asymmetry indicates a semantic tension: while monarch appears to geometrically mediate both gendered and political domains, the flow from female-associated terms deviates from the dominant axis. Nevertheless, monarch successfully subsumes the morphic circulation among king, queen, man, and woman, serving as a conceptual apex (Z-frame) that bridges the two word clusters:

```
[king, queen] ↔ [man, woman]
unified under the latent conceptual attractor: monarch
```

From a geometrical viewpoint, these divergences are positional errors relative to the apex. What appears as semantic tension in flat projection becomes, from the Z-frame's perspective, merely an expected distortion in projection space. The Z-frame does not require perfect symmetry; it requires coherence. And *monarch*, asymmetrically, holds.

Semantic Mediation via Z-frame: monarch

The Z-frame enables mediated and asymmetrically coherent morphic interpretation.

Let us define semantic transitions under Z = monarch.

```
man → woman | monarch  // gender role transformation within monarchic structure
woman → queen | monarch // woman becomes queen under monarchic mediation
queen → king | monarch  // queen transitions to king in the symbolic hierarchy
therefore:
man → king | monarch  // man maps to king under the monarchic frame
```

From the perspective of Left Kan Extension, *king* can also be understood as a lifted projection from *man*, crossing from a gendered lexical domain (generic gender space) to a political-royal domain (*king*) under the frame *monarch*.

```
Royal Domain ⇔ Gendered Domain
           F: Royalty
        king
                        man
                              (H,K: Femenization)
        H
                        K
                        V
      queen
                       woman
              monarch
            (Z-frame apex)
Left Kan Extension:
Lan_\sigma(man) = king
                      monarch
Lan_{\sigma}(woman) = queen \mid monarch
```

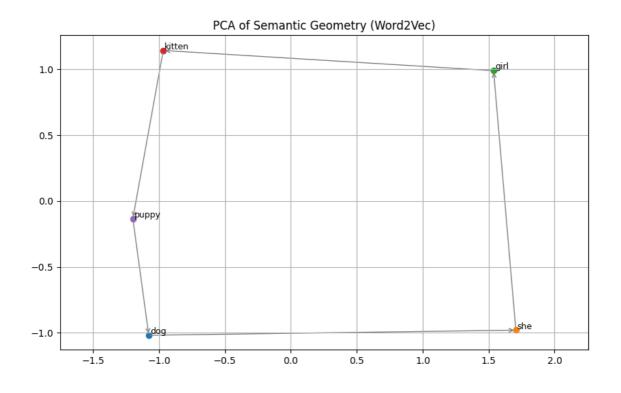

QNT Internal Z frame Induction

QNT has internal Z-frame coherence such that $f_1 \rightarrow f'_1 \mid Z_1$.

```
\begin{array}{lll} \eta\colon D_{i} \ \Rightarrow \ D_{i+1} & \big| \ \ CD \ = \ \ Mammal \\ \eta_{\_}X \ \circ \ D_{i}(\{f_{1} \ \big| \ Z_{1}, \ \ldots, \ f_{n} \ \big| \ Z_{n}\}) \ \approx \ D_{i+1}(\{f'_{1} \ \big| \ Z_{1}, \ \ldots, \ f'_{n} \ \big| \ Z_{n}\}) \ \circ \ \eta_{\_}Y \ \big| \ CD \\ for all \ f_{j} \colon \ X_{j} \ \Rightarrow \ Y_{j} \ \big| \ Z_{j} \ \in \ D_{i}, \\ where \ f'_{j} \colon \ \eta_{\_}X(X_{j}) \ \Rightarrow \ \eta_{\_}Y(Y_{j}) \ \big| \ Z_{j} \end{array}
```

Using the same method KMeans, we could induce internal Z-frame (or CD)-kitten using puppy, dog, girl and she.

```
=== Z-frame Candidates ===
    puppy : Similarity = 0.8759
        dog : Similarity = 0.8172
    kitten : Similarity = 0.7581
        pup : Similarity = 0.7549
        girl : Similarity = 0.7462
        puppies : Similarity = 0.7243
golden_retriever : Similarity = 0.7225
        pooch : Similarity = 0.7119
Pomeranian : Similarity = 0.7082
    chihuahua : Similarity = 0.7012
```

By introducing the concept *mammal*, the overall geometric structure of the lexical field underwent a notable transformation. We observe that *mammal* does not merely act as an added point—but as a semantic mediator that 3-dimensionally mediates two distinct morphic chains: she \rightarrow dog and girl \rightarrow kitten \rightarrow puppy.

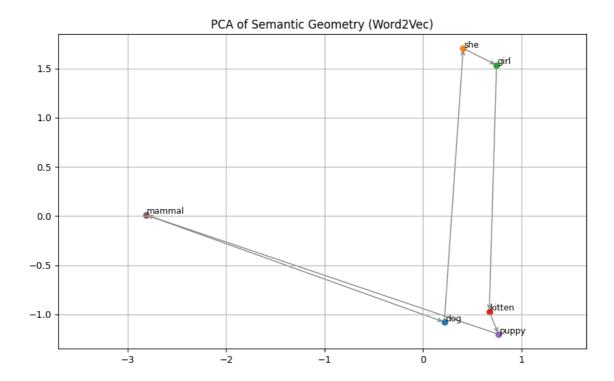

Diagram for visualization

While the geometric position of mammal is shifted from its PCA-projected location in this diagram, the topological structure of the semantic system remains intact—positioning mammal between two morphic chains, as visually observed in the PCA.

Conclusion

Conceptual Topos is a **fibered topos** over Z-frame:

```
CT := (C, B, \pi: E \rightarrow B, Fb := \pi^{-1}(b), A \cong b \cup Nat(Hom(-, A), Fb))
```

with:

- Initial Object "" \rightarrow codomain $\pi(X)$
- Morphic Chains as fibers $\pi^{-1}(Z)$
- Ω as subobject classifier in Z
- $\bullet \hspace{0.1in} \sigma$ operator inducing internal exponential morphisms.

Appendix

symbols

```
Z : Intermediating variable (conceptual anchor; Z-frame)
: Frame separator (indicates morphism is mediated by Z-frame)
→: Morphic Flow
→ / Ruptured morphism
F: Cross-category morphism (used in cross-category flow under shared Z-frame)
//: Used to narrate meaning flow of morphic chains.
¬: Absence
M|Z : Monoid of Conceptual Flow under Z-frame
R|Z := \{ rupture(f) \mid rupture(f, \sigma(f) \mid Z) \neq \emptyset \}
e|Z: Identity element of M|Z
D(A_{n-1} \mid Z): Morphic chain under Z frame
σ : Conceptual Shifting Morphism
>> : Generalization relation (A >> X ≡ A ⊑ X)
<<: Specialization relation (X >> A \equiv X \subseteq A)
rupture(f, \sigma(f) \mid Z) \neq \emptyset: Indicates conceptual rupture
η : Quasi-Natural Transformation: Contextual alignment between morphic chains.
\oplus: Conceptual morphism set addition in \sigma or morphic merger such as:
    (k_2 \circ k_1) \oplus (q_2 \circ q_1) = \text{human} \rightarrow \text{royalty} \mid Z'
⊖: Conceptual morphism set subtraction
    Removes specified morphisms from a morphic chain or set.
```

Notations

```
Concept / Word (lexeme):
    - Lower case (e.g., puppy, dog, girl, she)

Z Frame (conceptual anchor):
    - Upper case (e.g., Mammal, Human, Agency, Domesticated, Royalty)

Type variables (A, B, X, Y, Z in formal definitions):
    - Follow standard formal notation (uppercase)

Example:
puppy → dog | Mammal
A → B | Z

Morphism: f, g, h
Functor: F
```

Simplified Form of Identity Morphism:

```
    f: X → X | X (Category-theoretic identity)
    In simplified form: X
    or more explicitly: id_X
```

2. f: $X \rightarrow X \mid Z$ (Mediated identity with conceptual flow) In simplified form: $X \mid Z$

σ Operator

Conceptual Morphism Set Operators

```
Addition (\oplus): \sigma(X). \ \oplus (f, A_{n-1} \mid Z): \ D(A_{n-1} \mid Z) \to D(B_{n-1} \mid Z) \mid Z \sigma(X). \ \oplus (f_1, f_2): A_{n-1} := \{f_1, f_2\} Subtraction (\ominus): \ominus: A_{n-1} \ \ominus \{f_i\} \sigma(X). \ \ominus (f, A_{n-1} \mid Z): \ D(A_{n-1} \mid Z) \to D(B_{n-1} \mid Z) \mid Z - \ \oplus \ \text{operator is } \sigma_{\text{safe}} \ \text{if } Z \ \text{alignment is preserved.} - \ \ominus \ \text{operator is potentially } \sigma_{\text{unsafe}} \ \text{but can be } \sigma_{\text{safe}} \ \text{if resulting chain preserves the underlying morphic continuity } Z.
```

σ Typing Hierarchy

```
\sigma_{safe}: D(A<sub>n-1</sub> | Z) → D(B<sub>n-1</sub> | Z) | Z (Preserves global coherence)
\sigma_{safe}: D(A<sub>n-1</sub> | Z) → { rupture(f<sub>1</sub>), ..., rupture(f<sub>n</sub>) | ¬Z } (Global coherence lost)
```

Note: σ _safe behaves as Quasi-Natural Transformation. σ _unsafe induces rupture, and cannot be captured globally.

Python Code Used in This Study

```
import matplotlib.pyplot as plt
from sklearn.decomposition import PCA
from gensim.models import KeyedVectors
import numpy as np
model_path = ''
model = KeyedVectors.load_word2vec_format(model_path, binary=True)
words = ["this","dog"]
# ベクトル取得
vectors = [model[word] for word in words]
labels = words
# 次元削減 (PCA)
pca = PCA(n components=2)
reduced = pca.fit_transform(vectors)
# プロット
plt.figure(figsize=(10, 6))
for i, label in enumerate(labels):
    x, y = reduced[i]
    plt.scatter(x, y)
    plt.text(x + 0.01, y + 0.01, label, fontsize=9)
#矢印付加
from matplotlib.patches import FancyArrowPatch
for i in range(len(reduced) - 1):
    start = reduced[i]
    end = reduced[i + 1]
    arrow = FancyArrowPatch(start, end, arrowstyle='->', mutation scale=10,
color='gray')
    plt.gca().add_patch(arrow)
start = reduced[len(reduced)-1]
end = reduced[0]
arrow = FancyArrowPatch(start, end, arrowstyle='->', mutation_scale=10,
color='gray')
plt.gca().add_patch(arrow)
plt.title("PCA of Semantic Geometry (Word2Vec)")
plt.grid(True)
plt.axis("equal")
plt.savefig("image.png")
plt.show()
```

Kmeans

```
import numpy as np
from sklearn.cluster import KMeans
from gensim.models import KeyedVectors

model_path = ''
words = ["king", "queen", "man", "woman"]

model = KeyedVectors.load_word2vec_format(model_path, binary=True)
vectors = np.array([model[word] for word in words])

# KMeans Clustering
kmeans = KMeans(n_clusters=1, random_state=42, n_init='auto')
kmeans.fit(vectors)

# Z-frame
z_frame = kmeans.cluster_centers_[0]

print("\n=== Z-frame Candidates ===")
for word, score in model.similar_by_vector(z_frame, topn=10):
    print(f"{word:>12s} : Similarity = {score:.4f}")
```

Conceptual Topos Named as 概念位相論 / Conceptual Topology

This theory, named 概念位相論 or Conceptual Topoloy, was proposed by No Name Yet Exist.

Meaning no longer escapes.

It circulates within the morphic fibration.

We, once again, govern the topology of meaning.
